happened anyway or might be attributable to other factors). These steps need to be taken in consultation with identified key stakeholders and results verified with them. Actual calculation involves summation of positive impacts, subtraction of negative impacts and comparison with costs/investment. The findings from this study show:
The social return on investment is €15.85. In other words, every €1 spent on breastfeeding support groups returns €15.85 in social value.

Limitations
It is not possible to determine whether those randomly selected for inclusion were similar to all breastfeeding support groups in Ireland. In addition, information was not available about, or collected from, mothers who had stopped coming to the breastfeeding support groups. While there are many reasons mothers may stop attending (e.g. stopped breastfeeding, gone back to work, does not have time to attend), dissatisfaction with the group may also be a factor.

Areas for consideration
The findings from this study clearly highlight a number of benefits for key stakeholders, reflected in the positive return on investment of €15.85 for every €1 invested. It is clear that the facilitation of breastfeeding groups by PHNs has a demonstrable impact on maternal and child health. Based on these findings, the following areas should be considered:
1. Adopt a more systematised approach to the implementation of PHN-facilitated breastfeeding groups nationally to ensure equity of access for all breastfeeding mothers at local level.
2. PHN lactation consultants should be made universally available, and resourced, so that they can share their expertise with all PHNs providing a service for breastfeeding mothers.
3. A national policy on activities, processes and procedures for breastfeeding support groups should be developed to ensure consistency in how groups are implemented.
4. Consideration should be given to ensuring the premises, location and facilities available for breastfeeding support groups are a suitable environment for the delivery of the group.
5. Each PHN-facilitated group should be provided with a small amount of annual funding to ensure that basic equipment and facilities (e.g. baby mats, tea, coffee) are available at each breastfeeding group.
6. Local level information about the breastfeeding groups (e.g. leaflets with information about times, location and contact details) need to be made widely available and accessible.
7. It is recommended data on the frequency and outputs emerging from PHN-facilitated breastfeeding groups be collected and published.

Acknowledgements and thanks
This study was part-funded by the Institute of Community Health Nursing (ICHN). The Research Team are grateful to the ICHN and particularly to Ms Anne Lynott, President of the ICHN who facilitated our engagement with Public Health Nurses (PHNs) and who enabled ethics approval for this study. The Research Team gratefully acknowledge the help, insights and cooperation of the PHNs who made this study possible and who facilitated the research team to take account of the views of a wide range of stakeholders. We are especially thankful to them given their very busy workload and appreciate that they accommodated us in implementing this study.
A special thanks to all the breastfeeding mothers and their family members and friends who took part in this research. We express our appreciation to them for their time and willingness to share their experiences.
Aim of study
The overall aim of the project was to estimate the value of PHN-facilitated breastfeeding support groups. The research was informed by, and coherent with, the methodology used to calculate Social Return on Investment (SROI). This type of approach provides a framework for measuring and accounting for the broad concept of value by measuring changes in ways that are relevant to the people or organisations that experience or contribute to it.

Participants
This research focused on breastfeeding groups facilitated by PHNs in 11 locations across Ireland. Information was collected using qualitative and quantitative methods and data were collected from all relevant stakeholders. In total, 75 interviews (individual, joint and focus groups) were conducted with PHNs who facilitate a breastfeeding group (n=8), mothers currently attending a breastfeeding group (n=61), PHNs who do not facilitate a breastfeeding group but where mothers in their care attend one (n=3) and PHN managers (n=2). Surveys were completed by mothers (n=104), family and friends of mothers attending a PHN-facilitated breastfeeding group (n=16), PHNs who facilitate a breastfeeding group (n=11) and PHNs who do not facilitate a breastfeeding group but where mothers in their care attend one (n=8).

Findings: Inputs
Mothers attending the group were mainly aged between 30 to 40 years, had completed third-level education and about one in six had not been born in Ireland. Over 60% were first time mothers and a further 6% had not breastfed before although they had other children. About 30% of the 11 PHNs who facilitated groups had been doing so for more than five years, about 40% for three to five years and 30% for less than one year. Four of those included in the study had undertaken the required training to be a lactation consultant while the remaining PHNs had completed a range of training and education in breastfeeding. The groups were facilitated in different ways, including by one PHN (generally a lactation consultant), by two PHNs, and, in one case, by a rota of PHNs where each PHN facilitates the group every six to eight weeks. Facilitating a group was estimated to take zero to two hours by six of the PHNs and three to four hours by three PHNs.

Activities taking place at the groups
In summary, a range of activities were identified by PHNs and mothers as taking place before, during and after the breastfeeding group. While mothers could attend the group without a referral, it was noted that in general, they were told about it and referred to it by their PHN. Other less common sources of referrals included ante-natal classes where attending the breastfeeding group was an element for anyone wishing to breastfeed, GPs and maternity hospitals. In some instances where the same PHN was not in attendance each week, a rota had to be developed. On arrival at the venue, PHNs generally prepared the room which included putting out chairs, getting baby mats ready for use, making a weighing area available if that activity took place there, preparing tea and coffee and getting records ready. In a small number of instances, mothers spoke about getting childminding arrangements in place. The activities taking place at each breastfeeding group were very similar and five main activities were identified. These were:
- PHNs mediating the group;
- mothers socialising with each other;
- sharing information;
- one-to-one consultations with the PHN; and
- in eight of the 11 groups, weighing breastfeeding infants.

Outcomes and impact of attendance at the group
Two broad impacts of attendance at the breastfeeding support groups for mothers were identified and these were:
1. improved mental health (through having a purpose and reason to get out of the house, development of a social network, and feeling reassured and supported) and
2. breastfeeding for a longer period of time (through improvements in knowledge, confidence and through the normalisation of breastfeeding).

Social Return on Investment
Calculating an SROI for any programme of action involves a number of stages, notably (i) mapping outcomes and impacts for all relevant stakeholders (showing relationship between inputs, outputs and outcomes), (ii) verifying and putting a value on outcomes, and (iii) accounting for impacts that cannot be attributed to the programme (that might have
